## 1. Introduction

This report provides summarized results and analysis of the annual game count held on the NamibRand Nature Reserve and the Pro-Namib Conservancy on the 28th of May 2017. This is the 13th consecutive year that the count was held since its inception in 2005.

A game count briefing was held at the NamibRand Nature Reserve AGM on the day preceding the count where Control Warden Murray Tindall highlighted the objectives of the count and outlined the methodology and rules for the teams who would conduct the count. This helps to ensure consistency over consecutive years and allows a more accurate comparison from year to year.

Previous years data has been entered into a purpose designed database which generates the estimates used in this report in terms of total population, density and biomass. A few minor adjustments have been made to the database in order to improve its accuracy and this has slightly altered the figures for previous years as well as this years' count.

Surprisingly, even though this is the fifth year of drought the population estimates, as well as the overall density, showed marked increases this year. Individual populations of the two major grazers in this ecosystem, oryx and springbok, showed increases of $60 \%$ and $10 \%$ respectively. Overall, there was a significant increase in the majority of the different species populations this year ( $43 \%$ increase). However, the population of Ruppel's Korhaan was the only population that showed a decrease (36\%).

The distribution of animals across the reserve showed a slight trend of migration towards the northern parts of the NamibRand Nature Reserve. The majority of animals were concentrated near the north of the reserve, in plains/grassland areas (Zones 2, 3 and 4). The highest estimated populations of animals were seen in Zones 2 and 3.

It is worth reiterating that this census method is best suited to large plains game such as oryx, springbok and Burchell's zebra and is less suited to smaller species such as steenbok, or species with different habitat requirements such as kudu or mountain zebra. In addition, the estimates provided are intended to give an indication of population numbers and enable a comparison from year to year and may not be an entirely accurate reflection of the actual number of animals on the Reserve.

## 2. Summary

Data collected in the May 2017 game count was entered into our database and analyzed. The results are shown below bearing our three core objectives in mind:

## Objective 1: Population and biomass estimates:

Population estimates:
Table 1. Total number of game seen and the estimated numbers for May 2017.

| Total estimated numbers of game (Zone 1-10; May 2017) |  |  |
| :--- | ---: | ---: |
| Species | No. Counted | Estimate 2017 |
| Gemsbok | 2,847 | 10,625 |
| Springbok | 651 | 3,243 |
| Kudu | 1 | 4 |
| Steenbok | 0 | 0 |
| Ostrich | 76 | 226 |
| Ludwigs Bustard | 29 | 222 |
| Ruppel's Korhaan | 22 | 234 |
| B. Zebra | 347 | 717 |
| Hartebeest | 62 | 174 |
| Total | $\mathbf{4 , 0 3 5}$ | $\mathbf{1 5 , 4 4 5}$ |
| Giraffe* | 9 | 9 |

*Total numbers known

## Biomass estimates

Table 2. Wildlife biomass estimates for May 2017.

Total wildlife numbers and wildlife biomass on NamibRand for May 2017 (Zone 1-10) ; 224,209 ha)

| Species | Mean mass <br> $\mathbf{( k g )}$ | Estimated wildlife numbers <br> from May 2017 game count | Species biomass (kg) | Biomass per ha (kg) |
| :--- | ---: | ---: | ---: | ---: |
| Gemsbok | 220 | 10,625 | $2,337,500$ | 12.52 |
| Springbok | 38 | 3,243 | 123,234 | 0.66 |
| Kudu | 180 | 4 | 720 | 0.00 |
| Steenbok | 11 | 0 | 0 | 0.00 |
| Ostrich | 68 | 226 | 15,368 | 0.08 |
| B. Zebra | 300 | 717 | 215,100 | 1.15 |

| Giraffe* | 9 | 9 | 9 | 9 | $0 \%$ |

*Total (estimate) numbers known

## 3. Count Methodology

The primary objectives of the game count are to determine the density and distribution of game and to estimate the total number of game in a given, or total, area. For this reason, the survey methodology used is a combination of the road strip census and game distribution map techniques. In layman's terms, these can be explained as follows:

## Road strip count

This is one of the most effective methods to use when counting in a relatively open and homogenous landscape. For the purposes of the count, the total area is divided into game count zones, each with its own standardized route, as shown in Figure 1 on the next page. The game count zones were, as far as possible, deliberately predetermined into homogenous habitats because the visibility of animals differs in each habitat. Each route forms a strip transect through its zone within which the animals are counted. A transect width of 1 km is used ( 500 m on either side of the road). During the count, all animals on either side of the road are recorded, and the distances (at right angles to the vehicle and road) from the road to the animal or group of animals is recorded. These distance records are important, as they shape the effective strip width (ESW) values, which are automatically adjusted each year when data is entered into the database.
The length of the transect (distance traveled) and its relation to the area represented in the zone is used to calculate the area correction factors for each zone, i.e. area represented/route length $=$ area correction factor. The respective effective strip width (ESW) values and transect width then determines the relevant species correction factors, i.e. transect width (1000m) divided by (ESW x 2 ) = species correction factor. The area correction factors and species correction factors, adjusted by the relevant effective strip widths, i.e. how far each species is readily seen, is then used to calculate the population estimates. So basically, the area correction factor multiplies the number seen up based on the percentage of the area sampled and assumes all animals within 500 m of the transect line are detected. The species correction factor then adjusts this estimate based on the detection curve (ESW) for the species. The correction factors and route distances as used in the 2015 game count methodology, along with the area represented per zone can be seen in table 5 below.

Table 5. Total count areas per zone (ha), route distances, area correction factors, effective strip widths and species correction factors for each species within each zone for 2017.

| Count areas, area correction factors, effective strip widths and species correction factors |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Route No. | Total area perzone (ha) | Area <br> represented <br> per route | Route distance (km) | Area correction factor | Species | Effective strip width (m) | Species correction factor | Species | Effective strip width ( m ) routes 1-10 | 5pecies correction factor $(\mathrm{m})$ routes 1 - 10 |

Figure 1. The game count area shows the ten zones used in May 2017 for the NamibRand Nature Reserve (1-8, 10) and the Pro-Namib Conservancy (9).

## Game distribution maps

In order to determine and show the distribution and density of game in the various zones of the count area, monad grids are used to map the locality of the animals counted. Each route is supplied with a map containing the monad, with reference numbers, of the zone in which that route is set as seen in the image below.

During the count the monad grid number in which animal counted is seen, is recorded. This grid number is then used to map the distribution of each recorded animal.

Figure 2. Monad maps.

## 4. Objectives and results of the May 2017 count:

## Objective 1: Population and biomass estimates

## Population estimates:

The population estimates for individual species in the total count area are derived from the actual number of animals seen during the count and the relevant species and area correction factors that are applied to that number. The actual numbers seen is multiplied by the relevant area and species correction factors to get the population estimates.

S: Actual number of animals seen*
A: Area correction factor

Formula for calculating population estimates* $(\mathrm{S} \times \mathrm{A}) \times \mathrm{B}=\mathrm{P}$

B: Species correction factor
*Known numbers
Note that where total numbers of species with small populations are known (e.g. for recently introduced species such as red hartebeest, Burchell's zebra and giraffe), these known totals are used for the final population estimates in reference to the above calculated estimates.

The total estimates per species per zone were then combined for all zones in order to determine the total population estimate for each plains game species in the count area (see Table 1 below).

Table 1. Total number of game seen and the estimated numbers for May 2017.

| Total estimated numbers of game (Zone 1-10; May 2017) |  |  |
| :--- | ---: | ---: |
| Species | No. Counted | Estimate 2017 |
| Gemsbok | 2,847 | 10,625 |
| Springbok | 651 | 3,243 |
| Kudu | 1 | 4 |
| Steenbok | 0 | 0 |
| Ostrich | 0 | 226 |
| Ludwigs Bustard | 76 | 222 |
| Ruppel's Korhaan | 29 | 234 |
| B. Zebra | 22 | 717 |
| Hartebeest | 347 | 174 |
| Total | 62 | $\mathbf{1 5 , 4 4 5}$ |
| Giraffe* | $\mathbf{4 , 0 3 5}$ | 9 |
| *Toln | 9 | 9 |

*Total numbers known

Population estimates are multiplied by the mean weight of the species and divided by the total count area (ha) to get the estimated biomass per species.

E: Estimated wildlife numbers
M: Mean mass per species
H: Total no. of hectares

Formula for calculating biomass estimates
$($ ExM) $\div H=B$

B: Biomass estimate

Biomass estimates are important in terms of managing habitat conditions and inter-specific competition. Note that agricultural Livestock Units (LSU) are not used for determining the biomass of wildlife species, due to differences between domestic and wild animals. These two species are different in aspects such as grazing/browsing patterns and agricultural stocking. LSU are also in a fenced systems opposed to the open, unfenced system within the Reserve.

Tables 6.1, 6.2 and 6.3 below show the biomass estimates for this year, and the biomass estimates for previous years compared to this year.

Table 6.1 Wildlife biomass estimates for May 2017.

| Total wildlife numbers and wildlife biomass on NamibRand for May 2017 (Zone 1-10; 224,209 ha) |  |  |  |  |

## Objective 2: Wildlife density and distribution

To calculate the population density, the actual number of animals per species counted in each zone is divided by the respective route length and then multiplied by 100 to get the total number of animals seen per 100 km .

S: Actual number of animals seen
R: Length of route
K: Wildlife density - i.e. Animals seen per 100km driven

> Formula for calculating wildlife density $$
(S \div R) \times 100=K
$$

For the purposes of this report, wildlife distribution is based on the amount of animals seen in each monad.
During the game count, each sighting is marked to the corresponding monad the animal(s) was seen in. This data is then used to map the distribution of the animals (i.e. where animals were seen).

Please note that for the total wildlife distribution, all game species counted were used in the (mapping) calculation. The total wildlife (species) distribution and density are shown in the maps below. These densities were calculated using the formula prescribed above.
Note that the data is indicated on a gradient from light (low values) to dark (high values).

## Total wildlife population density for 2015-2017

Figure 6. Total wildlife density change from 2015-2017.

## Objective 3: Population change

The total estimated numbers of game for the May 2017 count is compared to those from previous years to illustrate the population change, and are shown in Tables 10 and 11 below. The overall population estimate has increased by $43 \%$ and the number of animals counted per 100 km per route has increased by $38.42 \%$.

Table 10. Population estimates for 2017 compared to 2016.

*Total numbers known

The graphs in figure 7.1-7.4 below, show the total long term individual estimate changes for the four most common species. Please note that the figures of these graphs are taken from the respective species estimates from the maximum number of routes counted in each year.

Figure 7.1
Gemsbok population change 2007-2017

Figure 7.2
Springbok population change 2007-2017

Figure 7.3
Burchell's zebra population change 2007 2017

Figure 7.4
Red hartebeest population change 2007-2017

The graph in Figure 8 below shows long term total population estimate change compared to the average annual rainfall received for the same period. Please note that as with the previous graphs, the figure for this graph was taken from the total population estimates and from the maximum number of routes counted in each year.

Figure 8. Total population change 2007 to 2017 compared to average rainfall.

## 5. Discussion and conclusions

## Gemsbok

The results of the 2017 gemsbok population estimate shows an increase of $59.77 \%$ ( 10,625 gemsbok) from last year's estimate ( 6,650 gemsbok). This is the first increase in gemsbok estimate numbers since 2014. While this is a significant increase in the population, it should be noted that there was an increase in rainfall in the central zones, thus causing an immigration of herds.

The highest density of gemsbok was recorded in Zone 4, which had a total of 1,138 gemsbok per 100 km . This is consistent with the previous two years indicating a preference for the habitat found in this zone. The second highest density of gemsbok was in Zone 6 (1,050 gemsbok per 100 km ). The higher densities of gemsbok in Zones 4 and 6 represents a southerly shift which is also seen in the previous year's data. In 2016, the highest densities were recorded in Zone 4 and Zone 7. The lowest density recorded in the 2017 population estimate was 50 gemsbok per 100 km , which was recorded in Zone 10. The second lowest density was recorded in Zone 9, 75 gemsbok per 100 km .

Overall, the population appears to be shifting slightly towards the central and southern parts of the reserve. These results follow trends in previous year's data, which indicates a shift from the northern part of the reserve, to the central and southern parts.

## Springbok

The estimated number of springbok for this year is 3,243 , which is an increase of $10.16 \%$ from last year's estimate of 2,944 . Although the estimated number of springbok is higher, the actual number of springbok seen has decreased from 690 in 2016 to 651 in 2017. This is a $6 \%$ decrease in springbok sightings.

The springbok were predominantly concentrated in Zones 4, 6 and 7. Of the estimated 3,243 springbok, there were 2,858 springbok or $63 \%$ of the total population in these zones. No springbok were accounted for in Zone 9 and only 8 springbok were estimated for Zone 10 . The other zones showed an average estimated population of 150 springbok.

## Kudu

Only one kudu was counted in this year's game count and an estimated population for the reserve is 4 . This estimated population does not give a true reflection of the kudu population, as sightings and camera trap images throughout the year suggest that there is a healthy population of kudu on the reserve. There was no kudu recorded during last year's game count and only two were recorded in 2015's game count. The game count method for this species is the most likely explanation for the fact that very few have been seen in the past three years.

## Steenbok

For the fourth year in a row, no steenbok have been seen during the game count. As the case with the kudus, the census method is not well suited for steenbok. Although no steenbok have been recorded, this is not a true reflection of the population on the reserve.

## Ostrich

This year's ostrich population estimate is 226 . This is an $56.9 \%$ increase from last year's population estimate of 145. The majority of the sightings were in Zone 6 ( 24 ostrich) and Zone 10 ( 27 ostrich), whereas no ostrich were recorded for Zones $1,2,8$ and 5 . This is the first increase in the population in more than five years.

## Ludwig's Bustard

The estimated number of Ludwig's Bustard increased from 92 in 2016 to 222 in 2017, a 141\% increase. This indicates a huge increase in the population size, something that has been seen throughout previous years. There are vast fluctuations in the Ludwig's Bustard estimated population size from year to year, and there are no trends to suggest a steady increase or decrease in the population.

## Ruppel's Korhaan

The estimated number of Ruppel’s Korhaan decreased from 362 in 2016 to 234 in 2017, a 35\% decrease. This decrease is most certainly attributable to the drought across the reserve. Overall, 22 Ruppel's Korhaan were seen this year as opposed to 29 last year.

## Burchell's Zebra

This is the second year calculated estimates were used to estimate the total population size for Burchell's zebra, since their range has expanded to cover most zones on the reserve. The Effective Strip Width (ESW) provides a greater visibility of Burchell's zebras and provided estimates that should closely resemble the total count number.

This year, a total of 347 zebra were counted to give a total estimated population of 717 . This is a $107 \%$ increase from 2016. As indicated previously the population is widespread throughout the reserve and zebra were only absent, or not counted, in Zones 9, 4, 3, and 1. Zone 2 had the highest density of 533 zebra per 100 km and accounted for more than half of the estimated population.

Burchell's zebra are considered less drought tolerant than gemsbok or springbok, but the population continued to increase. The increase in population is most likely attributable to their range expansion, coupled with the widespread provision of water in the reserve. The threshold has not yet been met for the zebra, but in the future their numbers will reach their threshold of tolerance and begin to decline.

## Red Hartebeest

The estimated number of red hartebeest increased from 149 in 2016 to 174 in 2017, a 16.78\% increase. This population estimate however might be a bit low, because they were only seen in two zones. There was 61 hartebeest seen in Zone 2 and only 1 seen in Zone 5.

## Giraffe

There were no giraffe sightings during this year's game count. Although there were no sightings there are regular sightings that suggest there are 9 giraffes on the reserve. There are 6 giraffes in the southern parts of the reserve, and 3 found in the northern parts of the reserve. It is unlikely that the population of giraffes will change in the near future, because the cows and bulls were separated during the relocation of a group of 4 to the southern part of the reserve.

## Total population change, distribution and densities

The total population estimate increased by $43.24 \%$ this year to 15,445 animals. The actual number of animals counted also increased from 2,915 animals in 2016 to 4,035 animals in 2017, an increase of $38.42 \%$. The increase in both the estimated and counted populations of animals is most likely due to the drought across the reserve. The reserve is currently in the longest consecutive period of below average rainfall since the inception of the game count in 2005.

From the data, it is possible to suggest that the estimated and counted populations increased due to the immigration of animals onto the reserve. The movement of animals suggests that the reserve has a more adequate water supply and better resources for the majority of animals, and the animals are most likely coming from a more drought-stricken regions. This increase in the total population size will lead to major increases in
competition for resources in the near future. The areas throughout the reserve will be depleted of its vital resources more quickly than usual due to the huge fluctuation in population size.

The overall density showed a $44.76 \%$ increase from the previous year and was consistent with the estimated population increase from previous years. This year, a total density of 760 animals per 100 km was observed compared to 525 in 2016. The overall distribution of animals across the reserve showed a slight trend of migration towards the northern parts of the NamibRand Nature Reserve.

## 6. Acknowledgments

The NamibRand Nature Reserve would like to thank all of its concessionaires, stakeholders, neighbors and participants for their enthusiastic involvement to make this year's game count another success.

This year's participants were:
Peter Woolfe, Etienne Rossouw, Elton Vries, Jaques Swartbooi, John Bernstein, Dominic
Fitzpatrick, Andrew Shapin, Willem Rooi, Eben Tsaobeb, Fritz Tsaobeb, Aloysis Hanse, Christiane Berker, Alex Boll, K. Garbade, Sakeus, H. Nghuumbwa, Bravo Kasupi, Bernhard, Quintin Hartung, Greg Yries, Manuella Schmid, Thomas Kelin, Kerstin Klein, Willie, Agnes, Elizabeth Johannes, Franziska Keresztesi, Esme, Elia, Nina and Ruben Bonifacious.

## 7. Appendix

## Results per count route per zone

Tables 12.1 to 12.10 list the data collected on each route in May 2017, which were used as a basis for the analysis.
